EXPERIMENT 9: AI-ASSISTED FEATURES & ZIA ANALYTICS IN ZOHO CREATOR

Aim

To explore AI-assisted analytics in the Insurance Claim Management System using dashboard metrics, visual charts, and Zia natural-language assistance to understand claim amounts, estimated payouts, risk scores, and claimant categories.

Overview

The Insurance Claim Management System contains claim records and a dashboard that summarizes important information. Analytics can help users understand total claim amounts, total payouts, average claim risk score, claimant types, and relationships between risk score and coverage percentage. Where Zia analytics is available, natural-language queries can be used to explore this data and generate insights.

Feature / Capability	Application in Insurance Claims
Dashboard Metrics	Summarize total amounts, total claim amount requested, total payouts, and average risk score.
Visual Analytics	Use charts to compare claimant types and visualize claim risk score against coverage percentage.
Zia Natural-Language Queries	Ask questions about claim data in natural language, if Zia analytics is enabled for the application.
Predictive Insights	Explore whether historical claim records support forecasting or anomaly detection, where the feature is available.

Procedure

1. Open the Application Dashboard: Open the existing Insurance Claim Management System in Zoho Creator and select the Dashboard page.

2. Review Summary Metrics: Check the dashboard cards for Total Amounts, Total Claim Amount Requested, Total Payouts, and Average Risk Score. Confirm that the displayed values reflect the current claim records.

3. Analyze Claimant Types: Review the Claimant Type summary for Nominee, Policyholder, Third Party, and Total. Use these counts to understand the distribution of claimants.

4. Review Visual Charts: Analyze the chart for Claim Risk Score by Coverage Percentage and the chart for Claimant Type by Coverage Percentage. Use the visuals to compare trends and category-level differences.

5. Explore Claim Records: Use the All Requests report to inspect individual claim records and compare fields such as Claimant Name, Claim Type, Date of Incident, Claim Amount Requested, and other available claim details.

6. Use Zia, if Available: If Zia analytics or natural-language querying is enabled in your account, try prompts such as: “Show total claim amount requested by claim type as a bar chart,” “Show average risk score by claimant type,” or “Identify unusually high claim amounts.” Review the results before relying on them.

7. Verify Results: Compare dashboard metrics and chart results with the underlying claim records. Treat forecasts or anomaly flags as decision-support information and verify them before making claim decisions.

Result

The Insurance Claim Management System dashboard was reviewed to summarize claim amounts, payouts, risk scores, claimant categories, and claim records. These visual analytics support clearer monitoring of claim data; Zia-based queries and predictive features can be used when enabled and available in the account.
